Complex Numbers

Derek, Vignesh

2020

COMPLEX NUMBERS [90 Marks]

- 1 Solve the following:
 - (a) Given that z = a + ib and w = c + id, where $a, b, c, d \in \mathbb{R}$,

(i) Show that
$$(zw)^* = z^*w^*$$
. [2]

We will perform algebraic manipulation of the given complex numbers using a,b,c,d

$$(zw)^* = [(a+ib)(c+id)]^* = [ac-bd+(bc+ad)i]^* = ac-bd-(bc+ad)i$$

 $z^*w^* = (a-ib)(c-id) = ac-bd-(bc+ad)i$ (Shown)

(ii) Hence, show that
$$(vzw)^* = v^*z^*w^*$$
 where $v \in \mathbb{C}$. [1]

Using the identity from above:

$$(vzw)^* = v^*(zw)^*$$
$$\therefore (vzw)^* = v^*z^*w^* \quad \text{(Shown)}$$

OR Let v = x + iy where $x, y \in \mathbb{R}$

$$(vzw)^* = [(x+iy)(ac - bd + (bc + ad)i)]^*$$

$$= [acx - bdx - (bc + ad)y + (bc + ad)xi]^*$$

$$= acx - bdx - (bc + ad)y - (bc + ad)xi$$

$$v^*z^*w^* = (x-iy)[ac - bd - (bc + ad)i]$$

$$= acx - bdx - (bc + ad)y - (bc + ad)xi$$
 (Shown)

(b) The locus of a parabola is given by $z = at^2 + i(2at)$ for $a, t \in \mathbb{R}$. Show that |z - a| = |Re(z) + a|.

We will just perform basic algebraic manipulation to prove this. Recall that the magnitude of a positive real number is the number itself and the magnitude of a complex number can be thought of as the distance from the origin of the complex number and is given by the equation $|z| = \sqrt{[\text{Re}(z)]^2 + [\text{Im}(z)]^2}$

$$|z - a| = |at^2 - a + i(2at)| = \sqrt{(at^2 - a)^2 + (2at)^2} = \sqrt{a^2t^4 + a^2 + 2(at)^2} = at^2 + a$$

 $|\operatorname{Re}(z) + a| = at^2 + a$ (Shown)

(c) It is given that $\operatorname{Im}(\frac{a+bi}{a-bi}) = 0$ for some $a, b \in \mathbb{R}$. Find the possible values of $\frac{a+bi}{a-bi}$.

When $\operatorname{Im}(\frac{a+bi}{a-bi}) = 0$, it means that the coefficient of i after performing algebraic manipulation of $\frac{a+bi}{a-bi}$ is 0. We first multiply the top and bottom of the given

fraction with the conjugate of the denominator.

$$\frac{a+bi}{a-bi} = \frac{(a+bi)(a+bi)}{(a-bi)(a+bi)} = \frac{a^2 - b^2 + 2abi}{a^2 + b^2}$$

$$\implies 2ab = 0 \implies a = 0 \text{ OR } b = 0$$

$$\therefore \frac{a+bi}{a-bi} = \pm 1$$

(d) For some $a, b \in \mathbb{R}$, $z^2 + az - b = 0$ has no real roots and $aw^2 + bw + a = 0$ has two real distinct roots. Given that a > 1, find an inequality satisfied by b. [3]

Recall that for any quadratic equation with real coefficients, the discriminant's value, Δ , defines the nature of its roots. Further recall that $\Delta = b^2 - 4ac$

$$\Delta(z^2 + az - b) = a^2 - 4(1)(-b) = a^2 + 4b < 0 \quad \text{(no real roots)}$$

$$\Delta(aw^2 + bw + a = 0) = b^2 - 4(a)(a) = b^2 - 4a^2 > 0 \quad \text{(2 distinct real roots)}$$

From the above equations we can glean that $b < \frac{-a^2}{4}$ and $b^2 > 4a^2$ which implies that b < -2a since $a > 1 \implies a^2 > 1$. Equating $\frac{a^2}{4} = 2a$:

$$\frac{a^2}{4} = 2a$$
$$a(a-8) = 0$$

For $1 < a \le 8$, $2a \ge \frac{a^2}{4}$ and for a > 8, $2a \le \frac{a^2}{4}$. This gives us the inequality below:

$$b < -2a, 1 < a \le 8$$

$$b < \frac{-a^2}{4}, a > 8$$

(e) It is given that
$$k = \frac{a-z^*}{z} + \frac{a-z}{z^*}$$
, where $z = a+ib$ for some $a,b \in \mathbb{R}$.
Show that $k = \frac{2b^2}{a^2+b^2}$.

We will just use the equation z = a + ib to solve this equation after making the denominator of the fractions to be $zz^* = |z|^2$

$$k = \frac{a - z^*}{z} + \frac{a - z}{z^*} = \frac{(a - z^*)z^*}{zz^*} + \frac{(a - z)z}{zz^*}$$

$$= \frac{a(z^* + z) - (z^*)^2 - z^2}{|z|^2}$$

$$= \frac{2a^2 - (a^2 - b^2 - 2abi) - (a^2 - b^2 + 2abi)}{a^2 + b^2}$$

$$= \frac{2b^2}{a^2 + b^2} \text{ (Shown)}$$

(f) Given that z = a + bi and w = b - ai, express v in terms of a and b if $v^* = \frac{z + w}{zw}$.

[3]

Recall that $\frac{1}{z} = \frac{z^*}{|z|^2}$. Let us apply this fact to find v^* and subsequently v.

$$v^* = \frac{z+w}{zw} = \frac{1}{z} + \frac{1}{w}$$

$$= \frac{z^*}{|z|^2} + \frac{w^*}{|w|^2}$$

$$= \frac{a-bi}{a^2+b^2} + \frac{b+ai}{a^2+b^2}$$

$$= \frac{a+b+(a-b)i}{a^2+b^2}$$

$$\implies v = \frac{a+b-(a-b)i}{a^2+b^2}$$

(g) Find $w \in \mathbb{C}$ in the equation $z^2 + wz + 2 = 0$ if one of the roots is i. [3]

We can just substitute z = i into this equation.

$$i^{2} + w(i) + 2 = -1 + wi + 2 = 0$$

 $\implies w = -1/i = i$

(h) For $a, b \in \mathbb{R}$ and $z \in \mathbb{C}$,

(i) Express $|(a-bi)^n|$ in terms of a, b and n. [2]

For any complex number z=a+bi, we can express it in polar form as $(\sqrt{a^2+b^2})e^{i\theta}$ where $\theta=\arg(z)$. Thus, $z^n=(a^2+b^2)^{\frac{n}{2}}e^{ni\theta}$ and it is evident that $|z^n|=(a^2+b^2)^{\frac{n}{2}}$. $\therefore |(a-bi)^n|=(a^2+b^2)^{\frac{n}{2}}$

(ii) Hence, if
$$(\sqrt{3} - \sqrt{2}i)^n = z$$
 where $|z| = 625$, find the value of n . [2] Given $(\sqrt{3} - \sqrt{2}i)^n = z$, we know that $|z| = (3+2)^{\frac{n}{2}} = 625 \implies \frac{n}{2} = 4 \implies n = 8$

2 Solve the following:

(a) Prove that
$$\operatorname{Re}(\frac{1}{e^{i\theta} + e^{-3i\theta}}) \equiv \frac{\cos \theta}{2\cos 2\theta}$$
. [4]

First, let us multiply the numerator and denominator of this fraction with $e^{i\theta}$. Then, we will use the fact that $e^{i\theta} = \cos \theta + i \sin \theta$ to prove this identity.

$$\frac{1}{e^{i\theta} + e^{-3i\theta}} = \frac{e^{i\theta}}{e^{2i\theta} + e^{-2i\theta}}$$

$$= \frac{\cos \theta + i \sin \theta}{2 \cos 2\theta}$$

$$\implies \operatorname{Re}(\frac{1}{e^{i\theta} + e^{-3i\theta}}) = \frac{\cos \theta}{2 \cos 2\theta} \quad \text{(Shown)}$$

(b) Show that
$$\frac{\csc\theta(\cot\theta+i)}{2\cos\theta(\cot\theta-i)} = \cot 2\theta + i.$$
 [4]

$$\frac{\csc\theta(\cot\theta+i)}{2\cos\theta(\cot\theta-i)} = \frac{(\cot\theta+i)}{2\sin\theta\cos\theta(\cot\theta-i)}$$

$$= (\csc2\theta)\frac{(\cot\theta+i)(\sin\theta)}{(\cot\theta-i)(\sin\theta)}$$

$$= (\csc2\theta)\frac{(\cos\theta+i\sin\theta)}{(\cos\theta-i\sin\theta)}$$

$$= (\csc2\theta)\frac{e^{i\theta}}{e^{-i\theta}}$$

$$= (\csc2\theta)e^{2i\theta}$$

$$= (\csc2\theta)(\cos2\theta+i\sin2\theta)$$

$$= \cot2\theta+i$$

3 Solve the simultaneous equations
$$zw = \frac{5}{2}(1+i)$$
 and $(1-i)w = \frac{iz+3}{2}$. [5]
Notice that we can remove w by taking $\frac{zw}{(1-i)w}$

$$\frac{zw}{(1-i)w} = \frac{5}{2}(1+i) \div \frac{iz+3}{2}$$
$$\frac{z}{1-i} = \frac{5(1+i)}{iz+3}$$
$$iz^2 + 3z = 10$$

Now we can collect z and apply the quadratic formula

$$iz^{2} + 3z - 10 = 0$$

$$z = \frac{-3 \pm \sqrt{3^{2} - 4(i)(10)}}{2i}$$

$$= \frac{-3 \pm \sqrt{9 - 40i}}{2i}$$

$$= \frac{-3 \pm (5 - 4i)}{2i}$$

$$= \frac{-8 + 4i}{2i} \quad \text{OR} \quad \frac{2 - 4i}{2i}$$

$$= 2 + 4i \quad \text{OR} \quad -2 - i$$

Let us substitute this value back into the first equation, $zw = \frac{5}{2}(1+i)$ to get w.

$$w_{1} = \frac{5(1+i)}{2(2+4i)}$$

$$= \frac{5(1+i)(2-4i)}{2(2+4i)(2-4i)}$$

$$= \frac{30-10i}{40}$$

$$= \frac{3-i}{4}$$

$$w_{2} = \frac{5(1+i)}{2(-2-2i)}$$

$$= \frac{5(1+i)(-2+2i)}{2(-2-2i)(-2+2i)}$$

$$= \frac{-20}{16}$$

$$= -\frac{5}{4}$$

When z + 2 + 4i, $w = \frac{3-i}{4}$ and when z = -2 - i, $w = -\frac{5}{4}$

4 It is given that $\arg(z^6(w^*)^5) = \frac{3\pi}{4}$. Given also that $|z^6(w^*)^5| = |z|$ and $z = \sqrt{3} + 3i$, find w.

Since this question consists of purely multiplying complex numbers, let us work in coordinate form:

$$z = \sqrt{3} + 3i = \sqrt{3^2 + 3} e^{i \tan^{-1} \sqrt{3}} = 2\sqrt{3} e^{i \frac{\pi}{3}}$$

We will use this to compute arg(w) and |z|

$$\arg(z^{6}(w^{*})^{5}) = 6\arg(z) - 5\arg(w)$$

$$= 2\pi - 5\arg(w)$$

$$= \frac{3\pi}{4}$$

$$\implies \arg(w) = \frac{\pi}{4}$$

$$|w| = \left(\frac{|z|}{|z|^{6}}\right)^{\frac{1}{5}}$$

$$= |z|^{-1}$$

$$= \frac{1}{2\sqrt{3}}$$

$$= \frac{\sqrt{3}}{6}$$

Thus,
$$w = \frac{\sqrt{3}}{6} e^{i\frac{\pi}{4}}$$

5 Given $k \in \mathbb{R}$ such that $\sqrt{11 + ki} = a + bi$, where a and b are positive real numbers,

(a) Express
$$k$$
 in terms of a . [2]

$$\sqrt{11 + ki} = a + bi$$

$$11 + ki = a^2 - b^2 + 2abi$$

Equating real and imaginary parts, we have

$$11 = a^2 - b^2 \implies b = \sqrt{a^2 - 11}$$
 and $k = 2ab$

[2]

Making k the subject, we have $k = 2a\sqrt{a^2 - 11}$

(b) Find the values of a and b if k = 60.

Substituting k = 60 into the equation found in (a),

$$60 = 2a\sqrt{a^2 - 11}$$

$$900 = (a^2)(a^2 - 11)$$

$$a^4 - 11a^2 - 3600 = 0$$

$$a = 6 \text{ (Using a G.C.)}$$
Using equation $b = \sqrt{a^2 - 11}, b = 5$

$$\therefore a = 6, b = 5$$

6 It is given that $z = 1 + e^{-i\frac{\pi}{4}}$.

(a) Show that
$$e^{-i\frac{3\pi}{4}} = -e^{i\frac{\pi}{4}}$$
. [1]

Recall that $e^{i\theta} = \cos \theta + i \sin \theta$

$$e^{-i\frac{3\pi}{4}} = \cos\frac{-3\pi}{4} + i\sin\frac{-3\pi}{4} = -\frac{\sqrt{2}}{2} - \frac{\sqrt{2}}{2}i$$

$$-e^{i\frac{\pi}{4}} = -(\cos\frac{\pi}{4} + i\sin\frac{\pi}{4}) = -(\frac{\sqrt{2}}{2} + \frac{\sqrt{2}}{2}i) = -\frac{\sqrt{2}}{2} - \frac{\sqrt{2}}{2}i \quad \text{(Shown)}$$

(b) Hence, find
$$(z-1)^3 + (z-1)^2 + z + i$$
. [3]

We will substitute the value of z into the expression and simplify the result using the answer from (a).

$$(z-1)^{3} + (z-1)^{2} + z + i = (1 + e^{-i\frac{\pi}{4}} - 1)^{3} + (1 + e^{-i\frac{\pi}{4}} - 1)^{2} + (1 + e^{-i\frac{\pi}{4}}) + i$$

$$= (e^{-i\frac{\pi}{4}})^{3} + (e^{-i\frac{\pi}{4}})^{2} + (1 + e^{-i\frac{\pi}{4}}) + i$$

$$= e^{-i\frac{3\pi}{4}} + e^{-i\frac{\pi}{2}} + 1 + e^{-i\frac{\pi}{4}} + i$$

$$= -e^{i\frac{\pi}{4}} + (-i) + 1 + e^{-i\frac{\pi}{4}} + i$$

$$= 1 - 2i(\sin\frac{\pi}{4})$$

$$= 1 - \sqrt{2}i$$

7 Given that 1+i is a root of the equation

$$4z^4 - 8z^3 + 17z^2 - 18z + 18 = 0.$$

find all the other roots in the form a + bi.

Since all coefficients of the quartic equation are real, 1-i is also a root of the given equation. Thus, the equation simplifies to:

$$4z^4 - 8z^3 + 17z^2 - 18z + 18 = [z - (1+i)][z - (1-i)](az^2 + bz + c) \quad \text{where} \quad a, b, c \in \mathbb{R}$$
$$= (z^2 - 2z + 2)(az^2 + bz + c)$$
$$= (z^2 - 2z + 2)(4z^2 + 9) = 0$$

Thus, the roots are $1 \pm i$ and $\pm \frac{3}{2}i$

8 The equation $3z^3 + az^2 + bz - 5 = 0$ has a root $z = \frac{1}{3}$, where a and b are real, non-zero constants.

Given that the sum of roots is $\frac{7}{3}$,

(a) Find the values of a and b.

[4]

Substitute $z = \frac{1}{3}$ into the equation to get:

$$3\left(\frac{1}{3}\right)^3 + a\left(\frac{1}{3}\right)^2 + b\left(\frac{1}{3}\right) - 5 = 0$$

$$\implies a + 3b = 44 - - - (1)$$

We can use the formula $\frac{a_2}{a_3} = -(\alpha + \beta + \gamma)$ where α, β, γ are roots of cubic polynomial $a_3x^3 + a_2x^2 + a_1x + a_0$.

Sum of Roots
$$= -\frac{a}{3} = \frac{7}{3}$$

 $\therefore a = -7$

Solving for b using (1) and a = -7, we get b = 17

(b) Find the remaining roots without using a calculator.

[2]

We now factorise out 3z - 1 from $3z^3 - 7z^2 + 16z - 5$. The remaining roots should form a conjugate pair.

$$3z^{3} - 7z^{2} + 16z - 5 = (3z - 1)(z^{2} - 2z + 5) = 0$$

$$z = \frac{2 \pm \sqrt{4 - 4(5)}}{2}$$

$$= \frac{2 \pm 4i}{2}$$

$$= 1 \pm 2i$$

The remaining roots are $1 \pm 2i$.

- **9** On an Argand diagram, referred from the origin O, points Z and W represent the complex numbers z = 1 + i and $w = -1 + \sqrt{3}i$ respectively. Points A and B represent Re(z) and Re(w) respectively.
 - (a) Express z and w in the form $re^{i\theta}$. [1] $z = \sqrt{2}e^{i\frac{\pi}{4}}, w = 2e^{i\frac{2\pi}{3}}$
 - (b) Find the area of trapezium BAZW. Hence or otherwise, find the area of ΔOZW .

[2]

Area of trapezium
$$BAZW = \frac{1}{2}(1+\sqrt{3})(2)$$

 $= (1+\sqrt{3}) \text{ units}^2$
Area of $\Delta OZW = \text{Area of trapezium } BAZW - \text{Area of } \Delta OAZ - \text{Area of } \Delta OBW$
 $= (1+\sqrt{3}) - \frac{1}{2}(1)(1) - \frac{1}{2}(1)(\sqrt{3})$
 $= (\frac{1+\sqrt{3}}{2}) \text{ units}^2$

(c) Hence, prove that
$$\sin \frac{5\pi}{12} = \frac{\sqrt{3} + 1}{2\sqrt{2}}$$
. [3]

Recall the formula for the area of Triangle $= \frac{1}{2}ab\sin C$. In our case, the two sides a and b are |z| and |w|. The angle C = angle OZW which is equal to $\arg(w) - \arg(z) = \frac{2\pi}{3} - \frac{\pi}{4} = \frac{5\pi}{12}$ on an Argand diagram.

Area of
$$\Delta OZW = \frac{1}{2}|z||w|\sin\frac{5\pi}{12}$$

$$= \frac{1}{2}(\sqrt{2})(2)\sin\frac{5\pi}{12}$$

$$= \sqrt{2}\sin\frac{5\pi}{12}$$

$$= \frac{1+\sqrt{3}}{2}$$

$$\therefore \sin\frac{5\pi}{12} = \frac{\sqrt{3}+1}{2\sqrt{2}}$$

10 Given that $e^{i\theta} = \cos \theta + i \sin \theta$,

(a) Show that
$$e^{i(3\theta)} = \cos 3\theta + i \sin 3\theta$$
. [1]

Replacing θ with 3θ , $e^{i(3\theta)} = \cos 3\theta + i \sin 3\theta$

(b) Find
$$\operatorname{Im}((\cos \theta + i \sin \theta)^3)$$
. [2]

$$(\cos \theta + i \sin \theta)^3 = {3 \choose 0} \cos^3 \theta + {3 \choose 1} i \cos^2 \theta \sin \theta - {3 \choose 2} \cos \theta \sin^2 \theta - {3 \choose 3} i \sin^3 \theta$$
$$= \cos^3 \theta + 3i \cos^2 \theta \sin \theta - 3 \cos \theta \sin^2 \theta - i \sin^3 \theta$$
$$\therefore \operatorname{Im}((\cos \theta + i \sin \theta)^3) = 3 \cos^2 \theta \sin \theta - \sin^3 \theta$$

(c) Using your answers in (a) and (b), express sin 3θ in terms of sin θ.
[2] sin 3θ can be found in the imaginary part of the answer in (a). We now equate this with the answer found in (b) and simplify the result.

$$\sin 3\theta = \operatorname{Im}((\cos \theta + i \sin \theta)^3)$$

$$= 3\cos^2 \theta \sin \theta - \sin^3 \theta$$

$$= 3(1 - \sin^2 \theta)(\sin \theta) - \sin^3 \theta$$

$$= 3\sin \theta - 4\sin^3 \theta$$

11 It is given that z = 1 + ki, where k > 0.

(a) Express z in the form $re^{i\theta}$. [2]

Since k > 0, arg (z) is in the first quadrant and thus it is simply $\tan^{-1} k$.

$$z = (\sqrt{1+k^2})e^{i\tan^{-1}k}$$

(b) Given that z^5 is a positive real number, find the value of k. [2]

$$\arg(z^5) = 5\arg(z)$$

$$= 5\tan^{-1}k$$

$$= n(2\pi), \text{ where } n \text{ is a non-negative integer}$$
Since $0 < \tan^{-1}k < \frac{\pi}{2} \implies 0 < 5\tan^{-1}k < \frac{5\pi}{2}, n = 1$

$$\therefore 5\tan^{-1}k = 2\pi \implies k = \frac{2\pi}{5}$$

12 The complex numbers z and w are given by $z = e^{i\frac{\pi}{6}}$ and $w = -1 - \sqrt{3}i$. If $\frac{z^2p^*}{w^3}$ is a positive real number and $\left|\frac{p^2w^2}{z^3}\right| = \frac{4}{9}$, find p in the form a + bi. [4]

We first convert w into polar form, which allows us to manipulate powers of complex numbers more easily. We then simplify the argument of $\frac{z^2p^*}{w^3}$ and modulus of $\frac{p^2w^2}{z^3}$ to find the argument and modulus of p.

With $z = e^{i\frac{\pi}{6}}$ and $w = 2e^{-i\frac{2\pi}{3}}$,

$$\arg\left(\frac{z^2p^*}{w^3}\right) = 2\arg\left(z\right) - \arg\left(p\right) - 3\arg\left(w\right)$$

$$= \frac{\pi}{3} - \arg\left(p\right) - (-2\pi)$$

$$= 2\pi$$

$$\therefore \arg\left(p\right) = \frac{\pi}{3}$$

$$\left|\frac{p^2w^2}{z^3}\right| = \frac{|p|^2|w|^2}{|z|^3}$$

$$= \frac{|p|^2(4)}{(1)}$$

$$= \frac{4}{9}$$

$$\therefore |p| = \frac{1}{3}$$

$$\therefore p = \frac{1}{3}(\cos\frac{\pi}{3} + i\sin\frac{\pi}{3}) = \frac{1}{6}(1 + i\sqrt{3})$$

13 In an Argand diagram, ABCDEF is a regular hexagon centred at the origin O where point A represents complex number a, B represents b, and so on. Given that a and d are purely real, and |a| = |d| = 4, find the area of:

(a) Rectangle
$$BCDF$$
; [2]

Area of rectangle
$$BCDF = (4)(2)(4\sin\frac{\pi}{3})$$

= $16\sqrt{3}$ units²

6 × Area of triangle
$$OAB = (6)(\frac{1}{2})(4)(4)(\sin \frac{\pi}{3})$$

= $24\sqrt{3}$ units²

- **14** The complex number z has modulus 2 and argument $-\frac{2\pi}{3}$.
 - (a) Sketch an Argand diagram showing the points P, Q and R representing z, z^2 and z^3 .

$$z = 2e^{-i\frac{2\pi}{3}} = -1 - \sqrt{3}i, z^{2} = 4e^{i\frac{2\pi}{3}} = -2 + 2\sqrt{3}i, z^{3} = 8e^{-2\pi i} = 8$$

$$Q(-2, 2\sqrt{3})$$

$$R(8, 0)$$

$$Re$$

$$-4$$

$$-2$$

$$2$$

$$4$$

$$6$$

$$8$$

(b) Using your diagram, find the area of ΔPQR .

[3]

We will use the formula, Area of Triangle = $\frac{1}{2}ab\sin C$, for each of the triangles ΔOPQ , ΔOQR and ΔORP and sum up the three areas.

Area of
$$\triangle PQR = \text{Area of } \triangle OPQ + \text{Area of } \triangle OQR + \text{Area of } \triangle ORP$$

$$= \frac{1}{2}|z||z^2|\sin\frac{2\pi}{3} + \frac{1}{2}|z^2||z^3|\sin\frac{2\pi}{3} + \frac{1}{2}|z^3||z|\sin\frac{2\pi}{3}$$

$$= \frac{1}{2}(\frac{\sqrt{3}}{2})(|z^3| + |z^4| + |z^5|)$$

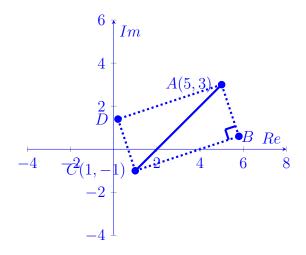

$$= \frac{\sqrt{3}}{4}|z^3|(1+|z|+|z^2|)$$

$$= \frac{\sqrt{3}}{4}(8)(1+2+4)$$

$$= 14\sqrt{3}\text{units}^2$$

- 15 In an Argand diagram, the points A, B, C and D represent complex numbers a = 5 + 3i, b, c = 1 i and d respectively such that ABCD is a circle described in a clockwise sense with AC as its diameter.
 - (a) Calculate the area of the circle ABCD. [2]

To visualise the problem, we will sketch an Argand diagram and plot the points A and C.

Area of circle
$$ABCD = \frac{1}{2}\pi r^2 = \frac{1}{2}\pi (\frac{1}{2}|a-c|)^2$$

$$= \frac{1}{8}\pi (|5+3i-(1-i)|)^2$$

$$= \frac{1}{8}\pi (\sqrt{4^2+4^2})^2$$

$$= 4\pi \text{ units}^2$$

(b) Given that
$$AB = 2BC$$
 and $AB = CD$, find b and d. [5]

The vectors \overrightarrow{BC} and \overrightarrow{BA} are represented by complex numbers c-b and a-b respectively. Recall that multiplying a complex number by i gives it a 90-degree anti-clockwise rotation. Given then BC is 2 times of BA and is rotated 90 degrees anti-clockwise from BA, we let b=x+iy and we have:

$$\overrightarrow{BC} = (2)(i)\overrightarrow{BA}$$

$$c - b = (2i)(a - b)$$

$$1 - i - x - iy = 2i(5 + 3i - x - iy)$$

$$(1 - x) + i(-1 - y) = (2y - 6) + i(-2x + 10)$$

Equating real and imaginary parts, 1 - x = 2y - 6 and -1 - y = 10 - 2x. Using a G.C., we obtain x = 5.8, y = 0.6.

$$b = 5.8 + 0.6i$$

Since $\overrightarrow{AB} = \overrightarrow{DC}$ we have:

$$b-a = c - d$$

$$d = c - b + a$$

$$= (1 - i) - (5.8 + 0.6i) + (5 + 3i)$$

$$= 0.2 + 1.4i$$
